In this tutorial I will describe how to write a simple MapReduce program for Hadoop in the Python programming language.

Motivation

Even though the Hadoop framework is written in Java, programs for Hadoop need not to be coded in Java but can also be developed in other languages like Python or C++ (the latter since version 0.14.1). However, Hadoop's documentation and the most prominent Python example on the Hadoop website could make you think that you must translate your Python code using Jython into a Java jar file. Obviously, this is not very convenient and can even be problematic if you depend on Python features not provided by Jython. Another issue of the Jython approach is the overhead of writing your Python program in such a way that it can interact with Hadoop – just have a look at the example in \$HADOOP_HOME/src/examples/python/MordCount.py and you see what I mean.

That said, the ground is now prepared for the purpose of this tutorial: writing a Hadoop MapReduce program in a more Pythonic way, i.e. in a way you should be familiar with.

What we want to do

We will write a simple MapReduce program (see also the MapReduce article on Wikipedia) for Hadoop in Python but without using Jython to translate our code to Java jar files.

Our program will mimick the WordCount, i.e. it reads text files and counts how often words occur. The input is text files and the output is text files, each line of which contains a word and the count of how often it occurred, separated by a tab

Note: You can also use programming languages other than Python such as Perl or Ruby with the "technique" described in this tutorial.

Prerequisites

You should have an Hadoop cluster up and running because we will get our hands dirty. If you don't have a cluster yet, my following tutorials might help you to build one. The tutorials are tailored to Ubuntu Linux but the information does also apply to other

- Running Hadoop On Ubuntu Linux (Single-Node Cluster) How to set up a pseudo-distributed, single-node Hadoop cluster backed by the Hadoop Distributed File System (HDFS)

Python MapReduce Code

The "trick" behind the following Python code is that we will use the Hadoop Streaming API (see also the corresponding wiki entry) for helping us passing data between our Map and Reduce code via STDIN (standard input) and STDOUT (standard output). We will simply use Python's sys.stdin to read input data and print our own output to sys.stdout. That's all we need to do because Hadoop Streaming will take care of everything else!

Map step: mapper.py

Save the following code in the file /home/hduser/mapper.pv, It will read data from STDIN, split it into words and output a list of lines mapping words to their (intermediate) counts to STDOUT. The Map script will not compute an (intermediate) sum of a word's occurrences though. Instead, it will output soords 1 tuples immediately—even though a specific word might occur multiple times in the input. In our case we let the subsequent Reduce step do the final sum count. Of course, you can change this behavior in your own scripts as you please, but we will keep it like that in this tutorial because of didactic reasons. :-)

Make sure the file has execution permission (chmod +x /home/hduser/mapper.py should do the trick) or you will run into problems

```
1 #!/usr/bin/env python
     # input comes from STDIN (standard input)
for line in sys.stdin:
    # remove leading and trailing whitespace
    line = line.strip()
    # split the line into words
0 words = line.split()
1    # increase counters
2    for word in words
2    # words words words to STDOUT (standard output):
    # where words there will be the input for the
5    # Reduce step, i.e. the input for reducer.py
    # #
                                         # tab-delimited; the trivial word count is 1
print '%s\t%s' % (word, 1)
```

Reduce step: reducer.py

Save the following code in the file /home/hduser/reducer.py. It will read the results of mapper.py from STDIN (so the output format of mapper.py and the expected input format of reducer.py must match) and sum the occurrences of each word to a final count, and then output its results to STDOUT.

Make sure the file has execution permission (chmod +x /home/hduser/reducer.py should do the trick) or you will run into problems.

- 1 #!/usr/bin/env python
- 3 from operator import itemgetter

1 of 6 05/12/2016 04:30 AM

```
4 import sys
9
10 # input comes from STDIN
11 for line in sys.stdin:
12 # remove leading and trailing whitespace
13 line = line.strip()
               # parse the input we got from mapper.py
word, count = line.split('\t', 1)
               # convert count (currently a string) to int
try:
              count = int(count)
except ValueError:
# count was not a number, so silently
# ignore/discard this line
continue
              # this IF-switch only works because Hadoop sorts map output
# by key (here: word) before it is passed to the reducer
if current_word == word:
    current_count += count
                        e:
    if current_word:
    # write result to STDOUT
    print "%s\%s" % (current_word, current_count)
current_count = count
current_word = word
34 current_word = word
35 current_word = word
38 if current_word == word:
38 if current_word == word:
39 print "%s\t\s' \% (current_word, current_count)
```

Test your code (cat data | map | sort | reduce)

I recommend to test your mapper. py and reducer. py scripts locally before using them in a MapReduce job. Otherwise your jobs might successfully complete but there will be no job result data at all or not the results you would have expected. If that happens, most likely it was you (or me) who screwed up.

Here are some ideas on how to test the functionality of the Map and Reduce scripts.

Test mapper.py and reducer.py locally first

```
1 # very basic test
2 hduser@ubuntu:~$ echo "foo foo quux labs foo bar quux" | /home/hduser/mapper.py
3 foo
4 foo
5 quux
6 labs
7 foo
8 bar
9 quux
 11 hduser/whothut:-$ echo "foo foo quux labs foo bar quux" | /home/hduser/mapper.py | sort -kl,1 | /home/hduser/reducer.py
14 labs 1
15 quux 2
16
17 # using one of the ebooks as example input
18 # (see below on where to get the ebooks)
19 # using one of the ebooks as example input
18 # (see below on where to get the ebooks)
20 The 1
21 Project 1
22 Gutenberg 1
23 EBook 1
24 of 1
25 [...]
26 (you get the idea)
```

Running the Python Code on Hadoop

Download example input data

We will use three ebooks from Project Gutenberg for this example

- The Outline of Science, Vol. 1 (of 4) by J. Arthur Thomson
- The Notebooks of Leonardo Da Vinci
- · Ulysses by James Joyce

 $Download\ each\ ebook\ as\ text\ files\ in\ {\tt Plain}\ {\tt Text}\ {\tt UTF-8}\ encoding\ and\ store\ the\ files\ in\ a\ local\ temporary\ directory\ of\ choice,\ for\ example\ {\tt /tmp/gutenberg}$

```
1 hduser@ubuntu:-$ ls -1 /tmp/gutenberg/
2 total 3604
3 -rw-r--r-1 hduser hadoop 674566 Feb 3 10:17 pg20417.txt
4 -rw-r--r-1 hduser hadoop 1573112 Feb 3 10:18 pg4300.txt
5 -rw-r--r-1 hduser hadoop 1423801 Feb 3 10:18 pg5000.txt
6 hduser@ubuntu:-$
```

Copy local example data to HDFS

Before we run the actual MapReduce job, we must first copy the files from our local file system to Hadoop's HDFS

```
\label{local-hadoop} $$ hduser@ubuntu:/usr/local/hadoop$ bin/hadoop $dfs -copyFromLocal /tmp/gutenberg /user/hduser/gutenberg hduser@ubuntu:/usr/local/hadoop$ bin/hadoop $dfs -ls $$
| hduser@ubuntu:/usr/local/hadoop$ bin/hadoop dfs -ls | found 1 items | duser_bubuntu:/usr/local/hadoop$ bin/hadoop dfs -ls | duser_tubuser/gutenberg | d 2010-05-08 17:40 /user/hduser/gutenberg | duser_tubuser/gutenberg | bduser@ubuntu:/usr/local/hadoop$ bin/hadoop dfs -ls /user/hduser/gutenberg | found 3 items | d 3 items | d 3 items | d 4 items | d 4 items | d 4 items | d 5 items | d 5
```

Run the MapReduce job

Now that everything is prepared, we can finally run our Python MapReduce job on the Hadoop cluster. As I said above, we leverage the Hadoop Streaming API for helping us passing data between our Map and Reduce code via STDIN and STDUUT

```
\label{lower_problem} $$1$ hower_public_solution_{1} hadoop_{1} bin/hadoop_{2} bin/hadoop_{2} bin/hadoop_{3} bin/hadoop_{3}
```

If you want to modify some Hadoop settings on the fly like increasing the number of Reduce tasks, you can use the -D option

2 of 6 05/12/2016 04:30 AM $1 \ hduser@ubuntu:/usr/local/hadoop\$ \ bin/hadoop\ jar\ contrib/streaming/hadoop-*streaming*.jar\ -D\ mapred.reduce.tasks=16\ \dots \ and \ another the contrib/streaming+hadoop-*streaming*.jar\ -D\ mapred.reduce.tasks=16\ \dots \ another the contrib/streaming+hadoop-*$

Note about mapred.map.tasks: Hadoop does not honor mapred.map.tasks beyond considering it a hint. But it accepts the user specified mapred.reduce.tasks and doesn't manipulate that. You cannot force mapred.map.tasks but can specify mapred.reduce.tasks.

The job will read all the files in the HDFS directory /user/hduser/gutenberg, process it, and store the results in the HDFS directory /user/hduser/gutenberg-output. In general Hadoop will create one output file per reducer; in our case however it will only create a single file because the input files are very small.

Example output of the previous command in the console:

```
1 hduser@ubuntu:/usr/local/hadoop$ bin/hadoop jar contrib/streaming/hadoop-*streaming*.jar -mapper /home/hduser/mapper.py -reducer /home/hduser/reducer.py -input /user/hduser/gutenberg-output 2 additionalConfSpec_inull
2 additionalConfSpec_inull
3 null-mo@user/abconfProps__get(stream.shipped.hadoopstreaming
4 packageJobJar: [/app/hadoop/tmp/hadoop-unjar54317]
5 [] /tmp/streamjob.Sf44] art tempir-mull
6 [...] INFO aspred.fileInputFormat: Total input paths to process : 7

```

As you can see in the output above, Hadoop also provides a basic web interface for statistics and information. When the Hadoop cluster is running, open http://localhost/50030/ in a browser and have a look around. Here's a screenshot of the Hadoop web interface for the job we just ran.

Hadoop job_200709211549_0003 on localhost

	Counter	Map	Reduce	Total
Job Counters	Launched map tasks	0	0	3
	Launched reduce tasks	0	0	1
	Data-local map tasks	0	0	3
Map-Reduce Framework	Map input records	77,637	0	77,637
	Map output records	103,909	0	103,909
	Map input bytes	3,659,910	0	3,659,910
	Map output bytes	1,083,767	0	1,083,767
	Reduce input groups	0	85,095	85,095
	Reduce input records	0	103,909	103,909
	Reduce output records	0	85,095	85,095

Change priority from NORMAL to: VERY HIGH HIGH LOW VERY LOW

Figure 1: A screenshot of Hadoop's JobTracker web interface, showing the details of the MapReduce job we just ran

Check if the result is successfully stored in HDFS directory /user/hduser/gutenberg-output

```
1 hduser@ubuntu:/usr/local/hadoop$ bin/hadoop dfs -ls /user/hduser/gutenberg-output
2 Found 1 items
3 /user/hduser/gutenberg-output/part-000000 6lt;r 16gt; 903193 2007-09-21 13:00
4 hduser@ubuntu:/usr/local/hadoop$
```

You can then inspect the contents of the file with the dfs -cat command:

Note that in this specific output above the quote signs (*) enclosing the words have not been inserted by Hadoop. They are the result of how our Python code splits words, and in this case it matched the beginning of a quote in the ebook texts. Just inspect the part-90000 file further to see it for yourself.

Improved Mapper and Reducer code: using Python iterators and generators

The Mapper and Reducer examples above should have given you an idea of how to create your first MapReduce application. The focus was code simplicity and ease of understanding, particularly for beginners of the Python programming language. In a real-world application however, you might want to optimize your code by using Python iterators and generators (an even better introduction in PDF).

Generally speaking, iterators and generators (functions that create iterators, for example with Python's yield statement) have the advantage that an element of a sequence is not produced until you actually need it. This can help a lot in terms of computational expensiveness or memory consumption depending on the task at hand.

Note: The following Map and Reduce scripts will only work "correctly" when being run in the Hadoop context, i.e. as Mapper and Reducer in a MapReduce job. This means that running the naive test command "cat DATA | /mapper.py | sort -k1,1 | /reducer.py" will not work correctly anymore because some functionality is intentionally outsourced to Hadoop.

Precisely, we compute the sum of a word's occurrences, e.g. ("foo", 4), only if by chance the same word (foo) appears multiple times in succession. In the majority of cases, however, we let the Hadoop group the (key, value) pairs between the Map and the Reduce step because Hadoop is more efficient in this regard than our simple Python scripts.

mapper.py

```
mapper.py (improved)
1 #!/usr/bin/env python
2 ***A more advanced Mapper, using Python iterators and generators.***
3
4 import sys
```

3 of 6 05/12/2016 04:30 AM

```
5
6 def read_input(file):
7 for line in file:
8 # split the line into words
9 yield line.split()
11 def main(separator='\t'):
12 # input comes from STDIN (standard input)
13 data = read_input(sys.stdin)
14 for words in data:
15 # write the results to STDOUT (standard output):
16 # what we output here will be the input for the
17 # Reduce step, i.e. the input for reducer.py
18 # **h-delimited; the trivial word count is 1
            11 def main(separator*\t'):
2  # input comes from STDII
3 data = read_input(sys.si
4 for words in data:

18  # Reduce step, i.e.
18  # ata-delinited; th
29  # tab-delinited;
21  print '%s%s\d' ?
22  if __name__ == "__main__":
24  __main()
                                                                    #
# tab-delimited; the trivial word count is 1
for word in words:
    print '%s%s%d' % (word, separator, 1)
```

reducer.py

```
reducer.py (improved)
          1 #!/usr/bin/env python
2 """A more advanced Reducer, using Python iterators and generators."""
          //
8 def read_mapper_output(file, separator='\t'):
9    for line in file:
10    yield line.rstrip().split(separator, 1)
9 to Line...
10 yield line.rstrip().spuzing...
11 zdef main(separator*\t'):
12 def main(separator*\t'):
13  # input comes from STDIN (standard input)
14 state - read_mapper_output(sys.stdin, separator-separator)
15  state - read_mapper_output(sys.stdin, separator-separator)
16  # and creates an iterator that returns consecutive keys and their group:
17  # current_word . string containing a word (the key)
18  # group - iterator yielding all [*@tt.current_wordsot;", "&ft.count&gf;"] items
19  for current_word, group in groupby(data, itemgeter(0)):
20  try:
21  total_count = sum(int(count) for current_word, count in group)
22  print "%sks%d" % (current_word, separator, total_count)
23  except ValueError:
24  # count was not a number, so silently discard this item
25  pass
26  pass
```
